

Web Experience Quality Score

Portfolio case study · WebOps · QA · Accessibility

ROLE	WebOps · Frontend QA · Accessibility · Product UX
PROJECT TYPE	Concept + Prototype
GOAL	Create a shared pre-launch quality model that helps teams prioritize web experience risks before publishing.

THE CHALLENGE

Launch reviews often live across separate checklists and tools. Passing one checklist does not necessarily mean the page provides a strong user experience.

Research & Problem Framing

WHAT I LOOKED AT

I grouped launch readiness into experience dimensions: usability, accessibility, responsive quality, performance, content/SEO, and release risk. The score is a prioritization aid, not a claim that quality can be reduced to one number.

KEY DECISIONS

- Show category scores and evidence rather than hiding everything behind a single grade.
- Prioritize high-impact issues before low-value polish.
- Separate automated checks from manual UX and accessibility validation.
- Provide a stakeholder summary alongside technical detail.
- Require retest and validation before an issue becomes ready.

DESIGN PRINCIPLE

Solve the user and workflow problem first. Use AI, automation, or visual change only where it makes the experience clearer, faster, safer, or easier to maintain.

Solution & Experience Decisions

THE SOLUTION

The prototype consolidates launch findings into a dashboard with category readiness, prioritized issues, ownership, and an AI-assisted summary based only on verified results.

ACCESSIBILITY & RESPONSIBLE DESIGN

Status is communicated with text and icons in addition to color, the interface supports keyboard use and reflow, and automated accessibility scores are never presented as proof of WCAG conformance.

FROM IDEA TO EXPERIENCE

1. Define the user or team problem and desired outcome.
2. Identify the smallest high-value changes or capabilities.
3. Make constraints visible: content, components, privacy, accessibility.
4. Prototype the critical journey and review it with experience owners.
5. Validate behavior and iterate before treating the concept as complete.

ANNOTATED CONCEPT

Measurement, Learnings & Next Iteration

HOW I WOULD MEASURE SUCCESS

Track high-severity issues caught pre-launch, escaped defects, repeated component issues, review cycle time, and percentage of launches completing manual quality validation.

WHAT I LEARNED

A useful quality system creates shared accountability. The score starts the conversation; evidence, ownership, and verification are what improve the experience.

NEXT ITERATION

Build a prototype report using a controlled set of checks, connect it to a manual review template, and test whether teams can prioritize launch decisions more consistently.

PROJECT PERSPECTIVE

How I Approach the Work

This project shows how I think about web quality as more than a final QA step. I wanted to bring usability, accessibility, responsive behavior, performance, and launch readiness together so teams can make better decisions before a page goes live.
