

AI-Assisted Page Builder

AI Product • CMS • Design Systems • UX

ROLE	Product Strategy, UX, Frontend Architecture, AI Workflow
PROJECT TYPE	AI product workflow concept
GOAL	Reduce enterprise web handoff friction by turning a page brief into structured, accessible recommendations using approved components.
STATUS	Product Concept + MVP

THE CHALLENGE

Enterprise page delivery often starts with disconnected notes, content requirements, design references, CMS constraints, and stakeholder requests. Teams spend time translating the same brief across marketing, UX, content, development, and QA.

Research & Problem Framing

WHAT I LOOKED AT

I decomposed the workflow into decisions AI can assist with versus decisions that require human ownership. Information architecture, component suggestions, content structure, and validation prompts can be accelerated; brand, legal, content approval, design judgment, and production release remain human-controlled.

WHY THIS MATTERS

The goal is not to add technology or visual polish for its own sake. The work should reduce friction, make decisions clearer, and give teams a repeatable way to improve the experience.

KEY DECISIONS

- Start with information architecture before visual component selection.
- Recommend only components from an approved library.
- Expose why a component was suggested and allow human override.
- Surface responsive and accessibility considerations before handoff.
- Export structured specifications rather than uncontrolled production code.

DESIGN PRINCIPLE

Solve the user and workflow problem first. Use AI, automation, or visual change only where it makes the experience clearer, faster, safer, or easier to maintain.

Solution & Experience Decisions

THE SOLUTION

The MVP takes page goal, audience, content needs, constraints, and approved component metadata. It proposes a content hierarchy, maps sections to allowed components, previews responsive intent, flags accessibility considerations, and exports a structured handoff for designers and developers.

ACCESSIBILITY & RESPONSIBLE DESIGN

Accessibility is treated as an early design constraint: heading order, content relationships, image alternatives, CTA and link purpose, component semantics, responsive reflow, and known component accessibility metadata are surfaced before build.

ANNOTATED CONCEPT

FROM IDEA TO EXPERIENCE

1. Define the user or team problem and desired outcome.
2. Identify the smallest high-value changes or capabilities.
3. Make constraints visible: content, components, privacy, accessibility, implementation.
4. Prototype the critical journey and review it with experience owners.
5. Validate behavior and iterate before treating the concept as complete.

Measurement, Learnings & Next Iteration

HOW I WOULD MEASURE SUCCESS	Evaluate time to first structured draft, number of handoff clarification cycles, component compliance, accessibility issues caught before development, and stakeholder satisfaction with the generated brief.
WHAT I LEARNED	The strongest role for AI in enterprise page building is not unrestricted generation. It is constrained orchestration: helping teams organize requirements and make approved patterns easier to use while humans retain judgment.
NEXT ITERATION	Create a functioning demo with a small component library, structured prompt schema, responsive preview, accessibility checks, and exportable JSON or Markdown handoff.

HOW I APPROACH THE WORK

This project reflects how I would use AI to reduce friction in enterprise web work. The goal is not to replace design or development decisions, but to help teams organize requirements, work with approved components, and move from an idea to a clearer handoff faster. This is an independent portfolio project. Where the concept has not been tested with real users or production data, I describe intended success measures rather than claiming verified business results.
