

Accessibility Intelligence Review

Portfolio case study · Accessibility · WCAG · UX

ROLE

Accessibility UX · Frontend QA · AI-assisted Review

PROJECT TYPE

Concept + Prototype

GOAL

Turn technical accessibility findings into prioritized guidance that teams can act on.

THE CHALLENGE

Automated accessibility tools can find certain failures, but their output may be technical, repetitive, and disconnected from user impact. Teams still need to understand what matters, why it matters, and how to verify a fix.

Research & Problem Framing

WHAT I LOOKED AT

I framed findings around affected users, severity, WCAG criterion, component ownership, remediation guidance, and retest status. Automated detection is evidence, not a complete accessibility verdict.

KEY DECISIONS

- Group findings by user impact and severity rather than raw error count.
- Translate each issue into plain-language experience impact.
- Keep WCAG references available for traceability.
- Use AI for explanation, not as the authority for accessibility conformance.
- Include retesting as part of the workflow.

DESIGN PRINCIPLE

Solve the user and workflow problem first. Use AI, automation, or visual change only where it makes the experience clearer, faster, safer, or easier to maintain.

Solution & Experience Decisions

THE SOLUTION

The prototype organizes issues into a workflow: scan, categorize, explain impact, recommend remediation, and retest. AI can summarize verified findings for different roles while deterministic checks and human testing remain authoritative.

ACCESSIBILITY & RESPONSIBLE DESIGN

The product itself must model accessible behavior through semantic structures, keyboard navigation, programmatic status, non-color severity cues, focus management, zoom/reflow support, and accessible alternatives for visual summaries.

FROM IDEA TO EXPERIENCE

1. Define the user or team problem and desired outcome.
2. Identify the smallest high-value changes or capabilities.
3. Make constraints visible: content, components, privacy, accessibility.
4. Prototype the critical journey and review it with experience owners.
5. Validate behavior and iterate before treating the concept as complete.

ANNOTATED CONCEPT

Measurement, Learnings & Next Iteration

HOW I WOULD MEASURE SUCCESS	Track time from finding to verified remediation, percentage of critical issues closed, repeated issues by component, false-positive review, and team understanding of user impact.
WHAT I LEARNED	Accessibility becomes easier to operationalize when teams share a common language connecting standards, user barriers, ownership, remediation, and verification.
NEXT ITERATION	Build a working prototype around a controlled demo page and validate the explanation layer with accessibility practitioners.

PROJECT PERSPECTIVE

How I Approach the Work

This project shows how I think about accessibility beyond just passing checks. I focus on understanding the real user impact, helping teams prioritize the right issues, and making the path from finding a problem to fixing and validating it easier to follow.
